Abstract

We develop a multigrid solver for the second biharmonic problem in the context of Isogeometric Analysis (IgA), where we also allow a zero-order term. In a previous paper, the authors have developed an analysis for the first biharmonic problem based on Hackbusch’s framework. This analysis can only be extended to the second biharmonic problem if one assumes uniform grids. In this paper, we prove a multigrid convergence estimate using Bramble’s framework for multigrid analysis without regularity assumptions. We show that the bound for the convergence rate is independent of the scaling of the zero-order term and the spline degree. It only depends linearly on the number of levels, thus logarithmically on the grid size. Numerical experiments are provided which illustrate the convergence theory and the efficiency of the proposed multigrid approaches.

1 Introduction

We consider multigrid methods for biharmonic problems discretized by Isogeometric Analysis (IgA). In particular, we consider the following model problem: Given a bounded domain $\Omega \subset \mathbb{R}^d$, $d \in \{2, 3\}$, with Lipschitz boundary $\partial \Omega$, a parameter $\beta \geq 0$ and sufficiently smooth functions $f, g_1,$ and $g_2$, find a function $u$ such that

$$\beta u + \Delta^2 u = f \quad \text{in} \quad \Omega,$$

$$u = g_1 \quad \text{on} \quad \partial \Omega,$$

$$\Delta u = g_2 \quad \text{on} \quad \partial \Omega$$

holds in a variational sense. For $\beta = 0$, this problem is known as the \textit{second biharmonic problem}, which is of interest for plate theory (cf. [6]) and Stokes streamline equations (cf. [9]). Problems with $\beta > 0$ are of particular interest in the context of optimal control problems, where the constraint is a second order elliptic operator. The optimality systems associated to these optimal control problems can be preconditioned robustly using preconditioners that rely on solving (1), see [18, 26, 1, 19]. The problem (1) is obtained when considering the full observation; if one considers an optimal control
problem with limited observation, one would obtain a similar problem, where the mass term \( \beta u \) is multiplied with the characteristic function for the observation domain.

We derive a standard variational formulation of the model problem, which lives in the Sobolev space \( H^2(\Omega) \). For the discretization, we use Isogeometric Analysis (IgA) since it easily allows for \( H^2 \)-conforming discretizations. Particularly, we consider a discretization based on tensor product B-splines of some degree \( p > 1 \) and maximum smoothness, i.e., \( p - 1 \) times continuously differentiable. For the derivation of the multigrid solver, we set up a hierarchy of grids as obtained by uniform refinement. Since we keep spline degree and spline smoothness fixed, we obtain nested spaces.

Concerning the choice of the smoother, there are many possibilities. We are interested in a smoother that yields a \( p \)-robust multigrid method. The first \( p \)-robust multigrid solvers were based on the boundary corrected mass smoother \cite{15} and the subspace corrected mass smoother \cite{14}. Both have been formulated for the Poisson problem. Since the subspace corrected mass smoother is more flexible and has proven itself more efficient in practice, we restrict ourselves to that smoother. The multigrid solvers with subspace corrected mass smoother have been extended to the first biharmonic problem in \cite{25} and to the second and third biharmonic problem in the thesis \cite{24}. The convergence estimates are shown using the standard splitting of the analysis into approximation property and smoothing property, as proposed by Hackbusch, cf. \cite{12}.

The theory in all of these papers requires that the grids are uniform since they have been based on the \( p \)-robust approximation error estimates from \cite{28}, which are valid only in this case. Since then, newer \( p \)-robust approximation error estimates, see \cite{23, 22}, have been proposed, which do not require uniform grids. Using these new estimates, it is straightforward to relax this assumption and to show analogous results for the Poisson problem as well as the first biharmonic problem for quasi uniform grids. However, this is not straightforward for the second biharmonic problem, since the proof requires a certain commutativity property (cf. \cite{24, Lemma 9.2}), which is only valid in case of uniform grids.

In this paper, we go another way. We base the analysis on the framework introduced by Bramble et al., cf. \cite{3, 2}. This allows us to drop the requirement that the grids are uniform. While this analysis could also be performed for other kinds of boundary conditions, like the first biharmonic problem, we restrict ourselves to the second biharmonic problem since it has previously turned out to be the more challenging one. For this setting, we prove a multigrid convergence estimate which is robust with respect to the spline degree \( p \) and which only depends logarithmically on the grid size \( h \).

Moreover, we show that the convergence is robust in the parameter \( \beta \geq 0 \). This analysis is motivated by the mentioned optimal control problem. Such parameter-robust multigrid solvers are also known for the Poisson problem, see \cite{20} for an analysis based on Hackbusch’s framework. There, the authors also provide a regularity result for the corresponding partial differential equation (PDE), which is based on standard results for the Poisson problem. In our case, we do not need to do that since Bramble’s analysis is
not based on any regularity assumptions.

In the numerical experiments, one can observe that the convergence of a multigrid solver with subspace corrected mass smoother degrades if the geometry gets distorted. While this is also true for the Poisson problem, this dependence is significantly amplified for the biharmonic problem. The reason for the geometry dependence of the convergence rates is that the subspace corrected mass smoother is based on the tensor product structure of the spline space. This tensor product structure is distorted by the geometry mapping. So, the contributions of the geometry function are ignored when setting up the smoother. We aim to overcome this problem by considering a hybrid smoother that combines the proposed smoother with Gauss-Seidel sweeps, see also [25, 24].

Alternative smoothers based on overlapping multiplicative Schwarz techniques have been considered in [7, 19]. Both approaches give good numerical results for the biharmonic problem. However, there is no rigorous, \( p \)-robust convergence theory available for these methods. It is worth mentioning that, as an alternative for solving biharmonic problems on the primal form, various kinds of mixed or non-conforming formulations have been developed, cf. [4, 29, 13, 21, 5].

The remainder of the paper is organized as follows. We introduce IgA, the biharmonic model problem in its variational form and its discretization in Section 2. In Section 3, the multigrid method is introduced and we state sufficient conditions for its convergence. We develop the approximation error estimates needed for the convergence estimates in Section 4. The choice of the smoother, the smoothing properties and the resulting multigrid convergence results are addressed in Section 5. Finally, we provide numerical results in Section 6.

2 Model problem and its discretization

2.1 The biharmonic model problem

Following the usual design principles of IgA, we assume that the computational domain \( \Omega \subset \mathbb{R}^d \) has a Lipschitz boundary \( \partial \Omega \) and that it is parameterized by a geometry function

\[
G : \hat{\Omega} = (0,1)^d \rightarrow \Omega = G(\hat{\Omega}),
\]

whose third weak derivatives are almost everywhere uniformly bounded. The parameterization has the property

\[
\| \nabla^r G \|_{L^\infty(\hat{\Omega})} \leq c_1 \quad \text{and} \quad \| (\nabla^r G)^{-1} \|_{L^\infty(\hat{\Omega})} \leq c_2, \quad \text{for} \quad r = 1, 2, 3, \tag{2.1}
\]

for some constants \( c_1 \) and \( c_2 \).

After homogenization, the variational formulation of the model problem [1] reads as follows. Given \( f \in L^2(\Omega) \) and \( \beta \in \mathbb{R} \) with \( \beta \geq 0 \), find \( u \in V := H^2(\Omega) \cap H_0^1(\Omega) \) such that

\[
\beta(u, v)_{L^2(\Omega)} + (\Delta u, \Delta v)_{L^2(\Omega)} = (f, v)_{L^2(\Omega)} \quad \forall v \in V. \tag{2.2}
\]
Here and in what follows, \( L^2(\Omega) \) and \( H^r(\Omega) \) denote the standard Lebesgue and Sobolev spaces with standard inner products \( \langle \cdot, \cdot \rangle_{L^2(\Omega)} \), \( \langle \cdot, \cdot \rangle_{H^r(\Omega)} \) and norms \( \| \cdot \|_{L^2(\Omega)} \), \( \| \cdot \|_{H^r(\Omega)} \). \( H^1_0(\Omega) \) is the standard subspace of \( H^1(\Omega) \) containing the functions with vanishing trace. On \( V \), we define the bilinear form \( \langle \cdot, \cdot \rangle_B \) via
\[
\langle u, v \rangle_B := \langle \Delta u, \Delta v \rangle_{L^2(\Omega)} \quad \forall \ u, v \in V,
\]
which is an inner product since we have the Poincaré like inequality
\[
\|u\|_{H^2(\Omega)} \leq c_\Omega \|\Delta u\|_{L^2(\Omega)} = c_\Omega \|u\|_B \quad \forall \ u \in V;
\] (2.3)
where \( c_\Omega \) is a constant that depends only on the shape of \( \Omega \), cf. [19].

Using the substitution rule for integration and the chain rule for differentiation, [3] can be expressed in terms of integrals on the parameter domain \( \Omega \). In IGA, this is usually done in order to simplify the evaluation of the integrals using quadrature rules. Besides these inner products, there are also standard inner products for the parameter domain, like \( \langle \cdot, \cdot \rangle_{L^2(\tilde{\Omega})} \) and \( \langle \cdot, \cdot \rangle_{\tilde{B}} \), where the latter is given by
\[
\langle \hat{u}, \hat{v} \rangle_{\tilde{B}} := \langle \Delta \hat{u}, \Delta \hat{v} \rangle_{L^2(\tilde{\Omega})} \quad \forall \ \hat{u}, \hat{v} \in \tilde{V} := H^2(\tilde{\Omega}) \cap H^1_0(\tilde{\Omega}).
\]

Also for the parameter domain \( \tilde{\Omega} \), the result (4) holds. So, we know
\[
\|u\|_{H^2(\tilde{\Omega})} \leq c_{\tilde{\Omega}} \|\Delta u\|_{L^2(\tilde{\Omega})} = c_{\tilde{\Omega}} \|u\|_{\tilde{B}} \quad \forall \ u \in \tilde{V}.
\]
We know (cf. [24]) that there exist constants \( c_M, c_B, \tilde{c}_M, \tilde{c}_B \) only depending on the constants \( c_1, c_2 \) and the shape of \( \Omega \) such that
\[
\begin{align*}
\ell_M (u, u)_{L^2(\Omega)} &\leq (\hat{u}, \hat{u})_{L^2(\tilde{\Omega})} \leq M (u, u)_{L^2(\Omega)} \quad \text{and} \\
\ell_B (u, u)_B &\leq (\hat{u}, \hat{u})_{\tilde{B}} \leq B (u, u)_B
\end{align*}
\] (2.4)
for all \( u \in V \) with \( \hat{u} = u \circ G \in \tilde{V} \). We define a simplified bilinear form \( \langle \cdot, \cdot \rangle_{\tilde{B}} \) as the inner product obtained by removing the cross terms from the inner product \( \langle \cdot, \cdot \rangle_{\tilde{B}} \), that is,
\[
\langle \hat{u}, \hat{v} \rangle_{\tilde{B}} := \sum_{k=1}^d \langle \partial_{x_k} \hat{u}, \partial_{x_k} \hat{v} \rangle_{L^2(\tilde{\Omega})} \quad \forall \ \hat{u}, \hat{v} \in \tilde{V}.
\]

Here and in what follows, \( \partial_x := \frac{\partial}{\partial x} \) and \( \partial_{xy} := \partial_x \partial_y \) and \( \partial_x^*: := \frac{\partial^*}{\partial x} \) denote partial derivatives. The original bilinear form and the simplified bilinear form are spectrally equivalent, which implies that also the simplified bilinear form is an inner product.

**Lemma 2.1.** The inner products \( \langle \cdot, \cdot \rangle_{\tilde{B}} \) and \( \langle \cdot, \cdot \rangle_{\tilde{B}} \) are spectrally equivalent, that is,
\[
(\hat{u}, \hat{u})_{\tilde{B}} \leq \ell (\hat{u}, \hat{u})_{\tilde{B}} \leq d (\hat{u}, \hat{u})_{\tilde{B}} \quad \forall \ \hat{u} \in \tilde{V}.
\]
Proof. From \([\Pi, [10]], it follows that \(\|\Delta \hat{u}\|_{L^2(\hat{\Omega})} = \|\nabla^2 \hat{\nu}\|_{L^2(\hat{\Omega})}\) for \(\hat{u}, \hat{\nu} \in \hat{V}\). Using this, we obtain
\[
\|\hat{u}\|_B^2 = \|\Delta \hat{u}\|_{L^2(\hat{\Omega})}^2 = \|\nabla^2 \hat{\nu}\|_{L^2(\hat{\Omega})}^2 = \sum_{k=1}^d \|\hat{c}_{xxk} \hat{u}\|_{L^2(\hat{\Omega})}^2 + \sum_{k=1}^d \sum_{l \in \{1, \ldots, d\} \setminus \{k\}} \|\hat{c}_{xxl} \hat{u}\|_{L^2(\hat{\Omega})}^2 \\
= \|\hat{\nu}\|_B^2
\]
which shows the first side of the inequality. Using the Cauchy-Schwarz inequality and \(ab \leq \frac{1}{2}(a^2 + b^2)\), we obtain
\[
\|\hat{u}\|_B^2 = \sum_{k=1}^d \sum_{l=1}^d \left(\hat{c}_{xxk}^2 \hat{u}, \hat{c}_{xil}^2 \hat{u}\right)_{L^2(\hat{\Omega})} \leq \frac{1}{2} \sum_{k=1}^d \sum_{l=1}^d \left(\|\hat{c}_{xxk} \hat{u}\|_{L^2(\hat{\Omega})}^2 + \|\hat{c}_{xil} \hat{u}\|_{L^2(\hat{\Omega})}^2\right) = d\|\hat{\nu}\|_B^2,
\]
which shows second side of the inequality. \(\Box\)

**Remark 2.1.** A analogous result holds for the domain \(\Omega\), which satisfies condition (2). In this case, the constants also depend on the shape of \(\Omega\).

### 2.2 Discretization

We consider a discretization using tensor product B-splines in the context of IgA. We start by defining these splines on the parameter domain \(\hat{\Omega}\). Let \(C^k(0, 1)\) denote the space of all continuous functions mapping \((0, 1) \to \mathbb{R}\) that are \(k\) times continuously differentiable and let \(P_p\) be the space of polynomials of degree at most \(p\). For any sequence of grid points \(\tau := (\tau_0, \ldots, \tau_{N+1})\) with
\[
0 = \tau_0 < \tau_1 < \cdots < \tau_N < \tau_{N+1} = 1,
\]
we define the space \(S_{p, \tau}\) of splines of degree \(p\) with maximum smoothness by
\[
S_{p, \tau} := \left\{ v \in C^{p-1}(0, 1) : |\tau_j, \tau_{j+1}| \in P_p, \ j = 0, 1, \ldots, N \right\}.
\]
The size of the largest and the smallest interval are denoted by
\[
h_{\tau} := \max_{j=0,\ldots,N} (\tau_{j+1} - \tau_j) \quad \text{and} \quad h_{\tau,\min} := \min_{j=0,\ldots,N} (\tau_{j+1} - \tau_j),
\]
respectively. For the parameter domain, we define a spline space by tensorization, which we transfer to the physical domain using the pull-back principle, thus we define for given sequences of grid points \(\tau_{t,1}, \ldots, \tau_{t,d}\) the spaces
\[
\hat{V}_t := \left(\bigotimes_{i=1}^d S_{p, \tau_{ti}}\right) \cap H^1_0(\hat{\Omega}) \subset \hat{V} \quad \text{and} \quad V_t := \{ f \circ G^{-1} : f \in \hat{V}_t \} \subset V.
\]
Here and in what follows, the tensor product space \(\bigotimes_{i=1}^d S_{p, \tau_{ti}}\) is the space of all linear combinations of functions of the form \(v(x_1, \ldots, x_d) = v_1(x_1) \cdots v_d(x_d)\) with \(v_i \in S_{p, \tau_{ti}}\).
The spline degree $p$ could be different for each of the spatial directions. For notational convenience, we restrict ourselves to a uniform choice of the degree.

The corresponding minimum and maximum grid size are denoted by

$$h_\ell := \max_{i=1,...,d} h_{\tau_{\ell,i}} \quad \text{and} \quad h_{\ell,\text{min}} := \min_{i=1,...,d} h_{\tau_{\ell,i,\text{min}}}.$$  

For the multigrid methods we, set up a sequence nested spline spaces

$$V_0 \subset V_1 \subset \cdots \subset V_L \subset V \quad \text{with} \quad h_0 > h_1 > \cdots > h_L > 0$$

based on a sequence of nested grids.

We assume that all grids are quasi uniform, that is, there is a constant $c_q$ such that

$$h_\ell \leq c_q h_{\ell,\text{min}} \quad \text{for} \quad \ell = 0, 1, \ldots, L. \quad (2.5)$$

We also assume that the ratio of the grid sizes of any two consecutive grids is bounded, that is, there is a constant $c_r$ such that

$$h_\ell \leq c_r h_{\ell-1} \quad \text{for} \quad \ell = 1, 2, \ldots, L. \quad (2.6)$$

If the grids are obtained by uniform refinements of the coarsest grid, then this condition is naturally satisfied with $c_r = 2$.

By applying a Galerkin discretization, we obtain the following discrete problem: Find $u_\ell \in V_\ell$ such that

$$\beta(u_\ell, v_\ell)_{L^2(\Omega)} + (u_\ell, v_\ell)_B = (f, v_\ell)_{L^2(\Omega)} \quad \forall v_\ell \in V_\ell. \quad (2.7)$$

By fixing a basis for the space $V_\ell$, we can rewrite (8) in matrix-vector notation as

$$(\beta M_\ell + B_\ell)u_\ell = f_\ell, \quad (2.8)$$

where $B_\ell$ is the biharmonic stiffness matrix, $M_\ell$ is the mass matrix, $u_\ell$ is the vector representation of the corresponding function $u_\ell$ with respect to the chosen basis and the vector $f_\ell$ is obtained by testing the right-hand side functional $(f, \cdot)_{L^2(\Omega)}$ with the basis functions.

**Notation 2.1.** Throughout this paper, $c$ is a generic positive constant that is independent of $h$ and $p$, but may depend on $d$, the constants $c_1$, $c_2$, $c_q$, and $c_r$ and the shape of $\Omega$.

For any two square matrices $A, B \in \mathbb{R}^{n \times n}$, $A \leq B$ means that

$$x^T A x \leq x^T B x \quad \forall x \in \mathbb{R}^n.$$ 

3 The multigrid solver

In this section, we present an abstract multigrid method and give a convergence theorem that is based on the analysis by Bramble et al., see [3 Theorem 1].
3.1 The multigrid framework

Let us assume that we have nested spaces $V_0 \subset V_1 \subset \cdots \subset V_L \subset V$. Let $I^{\ell}_{\ell-1}$ be the matrix representation of the canonical embedding from $V_{\ell-1}$ into $V_\ell$ and let the restriction matrix $I^{\ell-1}_{\ell}$ be its transpose, this is $I^{\ell-1}_{\ell} := (I^{\ell}_{\ell-1})^T$.

On each grid level, $\ell = 0, \ldots, L$, we have a linear system

$$A_\ell u_\ell = f_\ell,$$

which is obtained by discretizing a symmetric, bounded and coercive bilinear form $a(\cdot, \cdot)$ in the space $V_\ell$ using the Galerkin principle. The matrix induces a norm via $\|u_\ell\|_{A_\ell} := \|A^{1/2}_{\ell} u_\ell\|$. Here and in what follows, $(\cdot, \cdot)$ and $\|\cdot\|$ are the Euclidean scalar product and norm, respectively. In the continuous setting, the matrix can be represented by an operator $A : V \to V'$ with $Au = a(u, \cdot)$.

We have $\|u_\ell\|_A = \|u_\ell\|_{A_\ell}$ for all functions $u_\ell \in V_\ell$ with coefficient representation $u_\ell$.

For the analysis, we can additionally choose symmetric positive definite matrices $X_\ell$ for all grid levels $\ell = 0, 1, \ldots, L$, which induce norms via $\|u_\ell\|_{X_\ell} = \|(X^{1/2}_{\ell} u_\ell, u_\ell)_\ell\|$. The norm $\|u_\ell\|_{X_\ell}$ of a function $u_\ell \in V_\ell$ is interpreted as $\|u_\ell\|_{X_\ell}$, where $u_\ell$ is the coefficient representation of $u_\ell$.

For the abstract framework, we assume to have a symmetric and positive definite matrix $\tau_{\ell} L^{-1}_{\ell}$ for every grid level $\ell = 1, \ldots, L$, representing the smoother.

Later, for the model problem, the bilinear form $a(\cdot, \cdot)$, the matrices $A_\ell$, $\ell = 0, \ldots, L$ and our choice of $X_\ell$ will be

$$a(u, v) = \beta(u, v)_{L^2(\Omega)} + (u, v)_\mathcal{B}, \quad A_\ell = \beta \mathcal{M}_\ell + \mathcal{B}_\ell \quad \text{and} \quad X_\ell = (\beta + h^{-4}_\ell) \mathcal{M}_\ell + \mathcal{B}_\ell.$$

As smoothers, we will choose a subspace corrected mass smoother, a symmetric Gauss-Seidel smoother and a hybrid smoother in Section 5.

Based on these choices, the overall algorithm reads as follows.

**Algorithm 3.1.** One multigrid cycle, applied to some iterate $u_\ell^{(0)}$ and a right-hand side $f_\ell$ consists of the following steps:

- Apply $\nu_\ell$ pre-smoothing steps, i.e., compute

$$u_\ell^{(i)} = u_\ell^{(i-1)} + \tau_{\ell} L^{-1}_{\ell} (f_\ell - A_\ell u_\ell^{(i-1)}) \quad \text{for} \quad i = 1, \ldots, \nu_\ell. \tag{3.1}$$

- Apply recursive coarse-grid correction, i.e., apply the following steps. Compute the residual and restrict it to the next coarser grid level:

$$r_{\ell-1}^{(i)} = R^{\ell-1}_{\ell} (f_\ell - A_\ell u_\ell^{(i)})$$

The algorithm then proceeds to the next coarser level, $\ell$.

If \( \ell - 1 = 0 \), compute the update \( q_0 := A_0^{-1} x_0 \) using a direct solver. Otherwise, compute the update \( q_{\ell - 1} \) by applying the algorithm \( r \) \((r \in \mathbb{N} := \{1, 2, \ldots \})\) times recursively to the right-hand side \( x_{\ell - 1} \) and a zero vector as initial guess. Then set
\[
q_{\ell}^{(\nu_\ell + 1)} = q_{\ell}^{(\nu_\ell)} + I_{\ell - 1} q_{\ell - 1}^{(\nu_\ell)}.
\]

- Apply \( \nu_\ell \) post-smoothing steps, i.e., compute \( q_{\ell}^{(i)} \) using (10) for \( i = \nu_\ell + 2, \ldots, 2\nu_\ell + 1 \) to obtain the next iterate \( q_{\ell}^{(2\nu_\ell + 1)} \).

This abstract algorithm coincides with the algorithm presented in [3]. Since each multigrid cycle is linear, its application can be expressed by the matrix \( B^*_\ell \), which is recursively given by \( B^*_0 := A_0^{-1} \) and
\[
B^*_\ell := (I - (I - \tau_\ell L^{-1}_\ell A_\ell)^r (I - I_{\ell - 1} B^*_{\ell - 1} I_{\ell - 1}^{-1} A_\ell)^r (I - \tau_\ell L^{-1}_\ell A_\ell)^r) A^{-1}_\ell, \quad \ell = 1, \ldots, L.
\]

The iteration matrix corresponding to one multigrid cycle is given by
\[
I - B^*_\ell A_\ell = (I - \tau_\ell L^{-1}_\ell A_\ell)^r (I - I_{\ell - 1} B^*_{\ell - 1} I_{\ell - 1}^{-1} A_\ell)^r (I - \tau_\ell L^{-1}_\ell A_\ell)^r, \quad \ell = 1, \ldots, L.
\]

**Remark 3.1.** The integer \( r \) represents the recursively of the algorithm, where \( r = 1 \) corresponds to the V-cycle and \( r = 2 \) corresponds to the W-cycle.

### 3.2 Abstract convergence framework

The assumptions used to show convergence can be split into two groups: approximation properties and smoother properties.

**Theorem 3.1.** Let \( \lambda_\ell \) be the largest eigenvalue of \( X^{-1}_\ell A_\ell \). Assume that the following estimates hold:

- **Approximation properties.** There are constants \( C_1 \) and \( C_2 \), independent of \( \ell \), and linear operators \( Q_\ell : V_L \rightarrow V_\ell \) for \( \ell = 0, 1, \ldots, L \) with \( Q_L = I \) such that
  \begin{align}
  \| (Q_\ell - Q_{\ell - 1}) u_L \|^2_{X_\ell} &\leq C_1 \lambda^{-1}_\ell (u_L, u_L)_A \quad &\text{for} \quad \ell = 1, \ldots, L, \quad (3.2) \\
  (Q_\ell u_L, Q_{\ell - 1} u_L)_A &\leq C_2 (u_L, u_L)_A \quad &\text{for} \quad \ell = 0, \ldots, L - 1, \quad (3.3)
  \end{align}
  for all \( u_L \in V_L \).

- **Smother properties.** We assume there exist a constant \( C_S \) independent of \( \ell \) such that
  \[
  \frac{\| u_\ell \|^2_{X_\ell}}{\lambda_\ell} \leq C_S (\tau_\ell L^{-1}_\ell X_\ell u_\ell, u_\ell)_X \quad \forall u_\ell \in \mathbb{R}^{\dim V_\ell}
  \]
  and
  \[
  (\tau_\ell L^{-1}_\ell A_\ell u_\ell, u_\ell)_A \leq (u_\ell, u_\ell)_A \quad \forall u_\ell \in \mathbb{R}^{\dim V_\ell}
  \]
  holds for \( \ell = 1, \ldots, L \).
Then, the estimate
\[(I - B^T_L A_L w_L, w_L)_{A_L} \leq \left(1 - \frac{1}{CL}\right) (w_L, w_L)_{A_L},\]
holds for all \(w_L \in \mathbb{R}^{\dim V_L}\), where \(C = [1 + C_2^{1/2} + (C_SC_1)^{1/2}]^2\).
For a proof, see [3, Theorem 1].

**Remark 3.2.** Condition (13) is only required for functions \(w_\ell\) in the range of \(Q_\ell - Q_{\ell-1}\). However, since we do not exploit this, we have stated the stronger condition.

Now, we provide conditions that guarantee (13) and (14), which fit our needs better than the original conditions.

**Lemma 3.1.** If there exists a constant \(C_S\), independent of \(\ell\), which satisfies
\[(A_\ell w_\ell, w_\ell) \leq \frac{1}{\tau_\ell} (L_\ell w_\ell, w_\ell) \leq \lambda_\ell C_S (X_\ell w_\ell, w_\ell) \quad \forall w_\ell \in \mathbb{R}^{\dim V_\ell}\] (3.6)
for each \(\ell = 1, \ldots, L\). Then, the assumptions (13) and (14) hold for the same \(C_S\).

**Proof.** We start by showing that the first inequality implies (14), i.e., the smoothing operator \(I - \tau_\ell L_\ell^{-1} A_\ell\) is nonnegative in \(A_\ell\). Let \(w_\ell \in \mathbb{R}^{\dim V_\ell}\) be an arbitrary vector. Using the Cauchy-Schwarz inequality and the first inequality in (15), we obtain
\[
\tau_\ell (L_\ell^{-1} w_\ell, w_\ell) = \tau_\ell (A_\ell^{1/2} L_\ell^{-1} w_\ell, A_\ell^{-1/2} w_\ell) \\
\leq \tau_\ell (A_\ell L_\ell^{-1} w_\ell, L_\ell^{-1} w_\ell)^{1/2} (A_\ell^{-1} w_\ell, w_\ell)^{1/2} \\
\leq \tau_\ell^{1/2} (L_\ell^{-1} w_\ell, w_\ell)^{1/2} (A_\ell^{-1} w_\ell, w_\ell)^{1/2} \\
\leq \tau_\ell^{1/2} \lambda_\ell^{1/2} C_S^{1/2} (X_\ell^{-1} w_\ell, w_\ell)^{1/2} (L_\ell^{-1} w_\ell, w_\ell)^{1/2}.
\]
It follows that
\[
\tau_\ell (L_\ell^{-1} w_\ell, w_\ell) \leq (A_\ell^{-1} w_\ell, w_\ell) \quad \forall w_\ell \in \mathbb{R}^{\dim V_\ell}.
\]
By substituting \(w_\ell\) with \(A_\ell w_\ell\), we get (14). Next, we use the Cauchy-Schwarz inequality and the second inequality in (15) to show (13). Let \(w_\ell \in \mathbb{R}^{\dim V_\ell}\), we have
\[
(X_\ell^{-1} w_\ell, w_\ell) = (L_\ell^{1/2} X_\ell^{-1} w_\ell, L_\ell^{-1/2} w_\ell) \leq (L_\ell X_\ell^{-1} w_\ell, X_\ell^{-1} w_\ell)^{1/2} (L_\ell^{-1} w_\ell, w_\ell)^{1/2} \\
\leq \tau_\ell^{1/2} \lambda_\ell^{1/2} C_S^{1/2} (X_\ell^{-1} w_\ell, w_\ell)^{1/2} (L_\ell^{-1} w_\ell, w_\ell)^{1/2}.
\]
By squaring the inequality, we get
\[
(X_\ell^{-1} w_\ell, w_\ell) = \tau_\ell \lambda_\ell C_S (I_\ell^{-1} w_\ell, w_\ell) \quad \forall w_\ell \in \mathbb{R}^{\dim V_\ell}.
\]
By substituting \(w_\ell\) with \(X_\ell w_\ell\), we get (13). \qed
4 Approximation error estimates

In this section, we prove some approximation error estimates and provide a projector which will be used to prove (11) and (12).

4.1 Error and stability estimates for the univariate case

We start by introducing a periodic spline space. For any given sequence of grid points \( \tau = (0, \tau_1, \ldots, \tau_N, 1) \), we define

\[
\tau_{\text{per}} := (-1, -\tau_N, \cdots, -\tau_1, 0, \tau_1, \cdots, \tau_N, 1).
\]

For each \( p \in \mathbb{N} \), we define the periodic spline space

\[
S_{p, \tau}^{\text{per}} := \{ v \in S_{p, \tau} : \partial^l v (-1) = \partial^l v (1) \quad \forall l \in \mathbb{N}_0 \text{ with } l < p \},
\]

and a spline space with vanishing even derivatives on the boundary

\[
S_{p, \tau}^0 := \{ v \in S_{p, \tau} : \partial^{2l} v (0) = 0 \quad \forall l \in \mathbb{N}_0 \text{ with } 2l < p \}. \tag{4.1}
\]

We also define the periodic Sobolev space

\[
H^q_{\text{per}} (-1, 1) := \{ v \in H^q (-1, 1) : \partial^l v (-1) = \partial^l v (1), \quad \forall l \in \mathbb{N}_0 \text{ with } l < q \}
\]

for each \( q \in \mathbb{N} \). Let \( \Pi_{p, \tau}^{\text{per}} : H^2_{\text{per}} (-1, 1) \to S_{p, \tau}^{\text{per}} \) be the \( H^2 \)-orthogonal projector satisfying

\[
(\partial^2 \Pi_{p, \tau}^{\text{per}} u, \partial^2 v)_{L^2 (-1, 1)} = (\partial^2 u, \partial^2 v)_{L^2 (-1, 1)} \quad \forall v \in S_{p, \tau}^{\text{per}},
\]

\[
(\Pi_{p, \tau}^{\text{per}} u, 1)_{L^2 (-1, 1)} = (u, 1)_{L^2 (-1, 1)}. \tag{4.2}
\]

We use the following approximation error estimate for spline spaces which does not require uniform knot spans.

**Theorem 4.1.** For any \( p \geq 3 \), we have

\[
\| \partial^2 (u - \Pi_{p, \tau}^{\text{per}} u) \|_{L^2 (-1, 1)} \leq \frac{h^2}{\pi^4} \| \partial^4 u \|_{L^2 (-1, 1)} \quad \forall u \in H^4_{\text{per}} (-1, 1).
\]

For a proof, see [22, Theorem 4].

Using the \( H^2 - H^4 \) result above and an Aubin-Nitsche duality trick, we obtain the following \( L^2 - H^2 \) result.

**Theorem 4.2.** For any \( p \geq 3 \), we have

\[
\| u - \Pi_{p, \tau}^{\text{per}} u \|_{L^2 (-1, 1)} \leq \frac{h^2}{\pi^2} \| \partial^2 u \|_{L^2 (-1, 1)} \quad \forall u \in H^2_{\text{per}} (-1, 1).
\]
4 APPROXIMATION ERROR ESTIMATES

Proof. Let \( u \in H^2_{\text{per}}(-1,1) \) be arbitrary but fixed. Let \( w \in H^4(\mathbb{R}) \cap H^3_{\text{per}}(-1,1) \) be such that \( \partial^4 w = u - \Pi^\text{per}_{p,\tau} u \). Note that \( \Pi \) gives \( 0 = (u - \Pi^\text{per}_{p,\tau} u, 1)_{L^2(-1,1)} = (\partial^4 w, 1)_{L^2(-1,1)} = \partial^3 w(-1) - \partial^3 w(1) \). So, we know that \( w \in H^4_{\text{per}}(-1,1) \).

Using integration by parts (which does not introduce boundary terms since \( \partial^4 w \)), we obtain

\[
\|u - \Pi^\text{per}_{p,\tau} u\|^2_{L^2} = \left( u - \Pi^\text{per}_{p,\tau} u, \partial^4 w \right)_{L^2} = \left( \partial^2 (u - \Pi^\text{per}_{p,\tau} u), \partial^2 w \right)_{L^2} \leq \frac{h^2}{\pi^2} \|\partial^2 (u - \Pi^\text{per}_{p,\tau} u)\|_{L^2} \|\partial^2 w\|_{L^2},
\]

From the definition of \( \Pi^\text{per}_{p,\tau} \), see \( \Pi \), we have \( (\partial^2 (u - \Pi^\text{per}_{p,\tau} u), \partial^2 \Pi^\text{per}_{p,\tau} w)_{L^2} = 0 \). This, together with the Cauchy-Schwarz inequality and the \( H^2 \)-stability of \( \Pi^\text{per}_{p,\tau} \), gives

\[
\|u - \Pi^\text{per}_{p,\tau} u\|^2_{L^2} \leq \frac{h^2}{\pi^2} \|\partial^2 w\|_{L^2} \leq \frac{h^2}{\pi^2} \|\partial^2 w\|^2_{L^2},
\]

which completes the proof. \( \square \)

Let \( \Pi^0_{p,\tau} : H^2(0,1) \cap H^1_0(0,1) \to S^0_{p,\tau} \) be the \( H^2 \)-orthogonal projector satisfying

\[
(\partial^2 \Pi^0_{p,\tau} u, \partial^2 v)_{L^2(0,1)} = (\partial^2 u, \partial^2 v)_{L^2(0,1)} \quad \forall v \in S^0_{p,\tau}.
\]

Theorem 4.3. For any \( p \geq 3 \), we have

\[
\|u - \Pi^0_{p,\tau} u\|_{L^2(0,1)} \leq \frac{h^2}{\pi^2} \|\partial^2 u\|_{L^2(0,1)} \quad \forall u \in H^2(0,1) \cap H^1_0(0,1).
\]

Proof. Let \( u \in H^2(0,1) \cap H^1_0(0,1) \) be arbitrary but fixed. Define \( w \) on \((-1,1)\) to be

\[
w(x) := \text{sign}(x) \ u(|x|).
\]

Observe that we obtain \( w \in H^2_{\text{per}}(-1,1) \). From Theorem 4.2 we have

\[
\|(I - \Pi^\text{per}_{p,\tau} w)\|_{L^2(-1,1)} \leq ch^2 \|\partial^2 w\|_{L^2(-1,1)}.
\]

Observe that \( \|\partial^2 w\|_{L^2(-1,1)} = 2^{1/2} \|\partial^2 u\|_{L^2(0,1)} \). Define \( w_{\tau} := \Pi^\text{per}_{p,\tau} w \) and let \( u_{\tau} \) be the restriction of \( u \) to \((0,1)\). Observe that \( w_{\tau} \) is anti-symmetric, which implies that \( u_{\tau} \in S^0_{p,\tau} \). It follows that \( \|w - w_{\tau}\|_{L^2(-1,1)} = 2^{1/2} \|w - u_{\tau}\|_{L^2(0,1)} \). Using this, we obtain

\[
\|w - u_{\tau}\|_{L^2(0,1)} \leq ch^2 \|\partial^2 w\|_{L^2(0,1)}.
\]
It remains to show that $u_\tau$ coincides with $\Pi_{p,\tau}^0 u$, i.e., to show that $u - u_\tau$ is $H^2$-orthogonal to $S_{p,\tau}^0$. By definition, this means that we have to show

$$\langle \partial^2(u - u_\tau), \partial^2 u_\tau \rangle_{L^2(0,1)} = 0 \quad \forall u_\tau \in S_{p,\tau}^0.$$ 

Let $\tilde{w}_\tau \in S_{p,\tau}^{pr}$ be $\tilde{w}_\tau := \text{sign}(x) \tilde{u}_\tau(|x|)$ and observe that $2\langle \partial^2(u - u_\tau), \partial^2 \tilde{u}_\tau \rangle_{L^2(0,1)} = \langle \partial^2(w - w_\tau), \partial^2 \tilde{w}_\tau \rangle_{L^2(0,1)}$, since $u, u_\tau$ and $\tilde{u}_\tau$, respectively. Furthermore, $\langle \partial^2(w - w_\tau), \partial^2 \tilde{w}_\tau \rangle_{L^2(-1,1)} = 0$ by construction, since $w_\tau := \Pi_{p,\tau}^0 w$, which completes the proof.

Let $Q_{p,\tau}^0 : H^2(0,1) \cap H^1_0(0,1) \to S_{p,\tau}^0$ be the $L^2$-orthogonal projector satisfying

$$\langle Q_{p,\tau}^0 u, v \rangle_{L^2(0,1)} = (u, v)_{L^2(0,1)} \quad \forall v \in S_{p,\tau}^0.$$ 

Since the $L^2$-orthogonal projector minimizes the error in the $L^2$-norm, Theorem 4.3 immediately implies the following statement.

**Theorem 4.4.** For any $p \geq 3$, we have

$$\|u - Q_{p,\tau}^0 u\|_{L^2(0,1)} \leq \frac{h_\tau^2}{\tau^2} \|\partial^2 u\|_{L^2(0,1)} \quad \forall u \in H^2(0,1) \cap H^1_0(0,1).$$

Next, we show the stability of $Q_{p,\tau}^0$ with respect to the $H^2$-seminorm. Such a proof is possible since the space $S_{p,\tau}^0$ satisfies the following $p$-robust inverse inequality, while the space $S_{p,\tau} \cap H^1_0(0,1)$ does not satisfy such an inverse inequality, cf. [28].

**Theorem 4.5.** Let $p \in \mathbb{N}$ with $p \geq 2$. We have

$$\|\partial^2 u_\tau\|_{L^2(0,1)} \leq 12h_{\tau,\min}^{-2}\|u_\tau\|_{L^2(0,1)} \quad \forall u_\tau \in S_{p,\tau}^0.$$ 

A proof can be found in [25, Theorem 12].

**Theorem 4.6.** Let $p \in \mathbb{N}$ with $p \geq 3$. Then there exists a constant $c > 0$ such that

$$\|\partial^2(Q_{p,\tau}^0 u)\|_{L^2(0,1)}^2 \leq c\|\partial^2 u\|_{L^2(0,1)}^2 \quad \forall u \in H^2(0,1) \cap H^1_0(0,1).$$

**Proof.** The proof is analogous to that of [25, Theorem 14], however it is given here for completeness. Using the triangle inequality and the inverse inequality, we obtain

$$\|\partial^2 Q_{p,\tau}^0 u\|_{L^2}^2 \leq 2\|\partial^2 \Pi_{p,\tau}^0 u\|_{L^2}^2 + 2\|\partial^2(Q_{p,\tau}^0 u - \Pi_{p,\tau}^0 u)\|_{L^2}^2$$

$$\leq 2\|\partial^2 \Pi_{p,\tau}^0 u\|_{L^2}^2 + c h_{\tau,\min}^{-2}\|Q_{p,\tau}^0 u - \Pi_{p,\tau}^0 u\|_{L^2}^2$$

$$\leq 2\|\partial^2 \Pi_{p,\tau}^0 u\|_{L^2}^2 + c h_{\tau,\min}^{-2}\|u - \Pi_{p,\tau}^0 u\|_{L^2}^2 + c h_{\tau,\min}^{-2}\|u - Q_{p,\tau}^0 u\|_{L^2}^2.$$ 

The Theorems 4.3 and 4.4 and Assumption 6 give the desired result. \(\square\)
4.2 Proof of the approximation properties

In this subsection, we consider the discretization framework from Section 2. We choose

$$X_\ell := B_\ell + (\beta + h_\ell^{-4})M_\ell,$$

which corresponds to the norm \( \cdot \) \( X_\ell \) that satisfies

$$\| u \|_{X_\ell}^2 = \| u \|_B^2 + (\beta + h_\ell^{-4}) \| u \|_{L^2(\Omega)}^2 \quad \forall u \in V.$$

Now, we give a bound for the eigenvalues of \( X_\ell^{-1} A_\ell \).

**Lemma 4.1.** Let \( \lambda_\ell \) with \( \ell \geq 1 \) be the largest eigenvalue of \( X_\ell^{-1} A_\ell \). For \( p \geq 3 \), we have \( \lambda_\ell \in (\frac{1}{1+c}, 1) \) for some positive constant \( c \).

**Proof.** Since \( M_\ell \) is symmetric positive definite and \( h_\ell^{-4} \geq 0 \), we have \( A_\ell \leq X_\ell \), which implies \( \lambda_\ell \leq 1 \).

For the lower bound, we use \( V_{\ell-1} \subseteq V_\ell \), which implies that there is some \( w_\ell \in V_\ell \) that is \( L^2 \)-orthogonal to \( V_{\ell-1} \), that is \( (w_\ell, u_{\ell-1})_{L^2(\Omega)} = 0 \) for all \( u_{\ell-1} \in V_{\ell-1} \). By combining Theorem 4.7 and (5), we obtain

$$\| w_\ell \|_{L^2(\Omega)} = \sup_{u_{\ell-1} \in V_{\ell-1}} \| w_\ell - u_{\ell-1} \|_{L^2(\Omega)} \leq c h_{\ell-1}^2 \| w_\ell \|_B.$$ 

In matrix-vector notation, this reads as

$$w_\ell^T M_\ell w_\ell \leq c h_{\ell-1}^4 w_\ell^T B_\ell w_\ell.$$

Using (7), we know that there is a constant \( c > 0 \) such that

$$w_\ell^T X_\ell w_\ell = w_\ell^T A_\ell w_\ell + h_\ell^{-4} w_\ell^T M_\ell w_\ell < (1 + c) w_\ell^T A_\ell w_\ell,$$

which shows \( \lambda_\ell > 1/(1 + c) \).

Next, we prove (11) and (12). This requires that we choose the projectors \( Q_{p,\ell}^0 \), which have to map into the space \( V_\ell \). We first define a projector that maps from \( \hat{V} \) into \( \hat{V}_\ell \) by tensorization of the univariate projectors:

$$\hat{Q}_{p,\ell}^0 := Q_{p,\tau_1}^0 \otimes \cdots \otimes Q_{p,\tau_d}^0,$$

where the tensor product is to be understood as in [27, Section 3.2]. The next two theorems follow from Theorems 4.4 and 4.6 by standard arguments.

**Theorem 4.7.** Let \( p \in \mathbb{N} \) with \( p \geq 3 \). Then there exists a constant \( c \) such that

$$\| (I - \hat{Q}_{p,\ell}^0) \hat{u} \|_{L^2(\hat{\Omega})} \leq c h_\ell^2 \| \hat{u} \|_B \quad \forall \hat{u} \in H^2(\hat{\Omega}) \cap H_0^1(\hat{\Omega}).$$
Using Theorem 4.6, we further obtain
\[ \| (I - \hat{Q}_{p,\ell}^0) \hat{u} \|_{L^2(\hat{\Omega})} = \| (I - Q_{p,\tau_1}^0 \otimes Q_{p,\tau_2}^0) \hat{u} \|_{L^2(\hat{\Omega})} \]
\[ \leq \| (I - Q_{p,\tau_1}^0 \otimes I) \hat{u} \|_{L^2(\hat{\Omega})} + \| (Q_{p,\tau_1}^0 \otimes I)(I - I \otimes Q_{p,\tau_2}^0) \hat{u} \|_{L^2(\hat{\Omega})}. \]

Using the \( L^2 \)-stability of the \( L^2 \)-projectors, we further obtain
\[ \| (I - \hat{Q}_{p,\ell}^0) \hat{u} \|_{L^2(\hat{\Omega})} \leq \| (I - Q_{p,\tau_1}^0 \otimes I) \hat{u} \|_{L^2(\hat{\Omega})} + \| (I - I \otimes Q_{p,\tau_2}^0) \hat{u} \|_{L^2(\hat{\Omega})}. \]
The desired result immediately follows from Theorem 4.4. The extension to more dimensions is obvious. \( \square \)

**Theorem 4.8.** Let \( p \in \mathbb{N} \) with \( p \geq 3 \). Then there exists a constant \( c > 0 \) such that
\[ \| \hat{Q}_{p,\ell}^0 \hat{u} \|_{\mathcal{B}}^2 \leq c \| \hat{u} \|_{\mathcal{B}}^2 \quad \forall \hat{u} \in H^2(\hat{\Omega}) \cap H^1_0(\hat{\Omega}). \]

**Proof.** The proof is given for the two-dimensional case. We have by definition and using the triangle inequality
\[ \| \hat{Q}_{p,\ell}^0 \hat{u} \|_{\mathcal{B}}^2 = \| \hat{c}_{x_1}(Q_{p,\tau_1}^0 \otimes Q_{p,\tau_2}^0) \hat{u} \|_{L^2(\hat{\Omega})}^2 \]
\[ = \| \hat{c}_{x_1}(I \otimes Q_{p,\tau_2}^0)(Q_{p,\tau_1}^0 \otimes I) \hat{u} \|_{L^2(\hat{\Omega})}^2 + \| \hat{c}_{x_2}(Q_{p,\tau_1}^0 \otimes I)(I \otimes Q_{p,\tau_2}^0) \hat{u} \|_{L^2(\hat{\Omega})}^2. \]

Using the \( L^2 \)-stability of the \( L^2 \)-projector, we obtain
\[ \| \hat{Q}_{p,\ell}^0 \hat{u} \|_{\mathcal{B}}^2 \leq \| \hat{c}_{x_1}(I \otimes Q_{p,\tau_1}^0) \hat{u} \|_{L^2(\hat{\Omega})}^2 + \| \hat{c}_{x_2}(Q_{p,\tau_1}^0 \otimes I) \hat{u} \|_{L^2(\hat{\Omega})}^2. \]

Using Theorem 4.6, we further obtain
\[ \| \hat{Q}_{p,\ell}^0 \hat{u} \|_{\mathcal{B}}^2 \leq c \| \hat{c}_{x_1} \hat{u} \|_{L^2(\hat{\Omega})}^2 + c \| \hat{c}_{x_2} \hat{u} \|_{L^2(\hat{\Omega})}^2 = c \| \hat{u} \|_{\mathcal{B}}^2, \]
which finishes the proof. The extension to more dimensions is obvious. \( \square \)

The projectors \( Q_{p,\ell}^0 \) are now defined via the pull-back principle, such that
\[ Q_{p,\ell}^0 u := (\hat{Q}_{p,\ell}(u \circ G)) \circ G^{-1} \quad \forall u \in V. \tag{4.3} \]

Note that, by construction, \( Q_{p,\ell}^0 \) maps into a subspace of \( V_\ell \), where all even outer normal derivatives on the boundary vanish.

**Theorem 4.9.** Let \( d \in \mathbb{N} \) and \( p \in \mathbb{N} \) with \( p \geq 3 \). For each level \( \ell = 0, 1, \ldots, L - 1 \), let \( Q_{p,\ell}^0 : H^2(\Omega) \cap H^1_0(\Omega) \to V_\ell \) be the projectors defined in (18). There exists a constants \( C_1 \) and \( C_2 \) such that
\[ \| (Q_{p,\ell}^0 - Q_{p,\ell-1}^0) u_L \|_{X_\ell} \leq C_1 \lambda_{\ell}^{-1}(u_L, u_L)_A \quad \text{for } \ell = 1, \ldots, L, \tag{4.4} \]
\[ (Q_{p,\ell}^0 u_L, Q_{p,\ell}^0 u_L)_A \leq C_2(u_L, u_L)_A \quad \text{for } \ell = 0, \ldots, L - 1, \tag{4.5} \]
for all \( u_L \in V_\ell \).
Proof. Let \( u_L \in V_L \) arbitrary but fixed and let \( \hat{u}_L := \pi L \circ G \). Using (5), Lemma 2.1 and Theorem 4.4 and the \( L^2 \)-stability of \( Q_{p,\ell}^0 \), we obtain

\[
(Q_{p,\ell}^0 u_L, Q_{p,\ell}^0 u_L)_A \leq c(\hat{Q}_{p,\ell}^0 \hat{u}_L, \hat{Q}_{p,\ell}^0 \hat{u}_L)_A = c\beta \|\hat{Q}_{p,\ell}^0 \hat{u}_L\|_{L^2(\hat{\Omega})}^2 + c\|\hat{u}_L\|_{H^1(\hat{\Omega})}^2 \leq c(\hat{u}_L, \hat{u}_L)_A \leq C_2(u_L, u_L)_A,
\]

which shows (20). Next we prove the auxiliary result

\[
\| (I - Q_{p,\ell-1}^0) u_L \|_{X_L}^2 \leq c\lambda_{\ell-1}(u_L, u_L)_A \quad \text{for } \ell = 1, \ldots, L. \tag{4.6}
\]

Using (5), Lemma 2.1, Theorem 4.4, Theorem 4.7 and the \( L^2 \)-stability of \( Q_{p,\ell-1}^0 \), we get

\[
\| (I - Q_{p,\ell-1}^0) u_L \|_{X_L}^2 = \| (I - Q_{p,\ell-1}^0) u_L \|_{B}^2 + (\beta + h_{\ell-1}^4) \| (I - Q_{p,\ell-1}^0) u_L \|_{H^2(\Omega)}^2 \leq c\| (I - \hat{Q}_{p,\ell-1}^0 \hat{u}_L \|_{B}^2 + c(\beta + h_{\ell-1}^4) \| (I - \hat{Q}_{p,\ell-1}^0 \hat{u}_L \|_{H^2(\Omega)}^2 \leq c\| \hat{u}_L \|_{B}^2 + c h_{\ell-1}^4 \| \hat{u}_L \|_{B}^2 + c\| \hat{u}_L \|_{H^2(\Omega)}^2 \leq c(1 + h_{\ell-1}^4) \| u_L \|_{L^2(\Omega)}^2 + c\| u_L \|_{H^2(\Omega)}^2.
\]

We use assumption (7) and Lemma 4.1 to get (21). To complete the proof, we use the fact that \( Q_{p,\ell-1}^0 Q_{p,\ell}^0 = Q_{p,\ell-1}^0 \), (21) and (20), to obtain

\[
\| (Q_{p,\ell}^0 - Q_{p,\ell-1}^0) u_L \|_{X_L}^2 = \| (I - Q_{p,\ell-1}^0) Q_{p,\ell}^0 u_L \|_{X_L}^2 \leq c\lambda_{\ell-1}^{-1}(Q_{p,\ell}^0 u_L, Q_{p,\ell}^0 u_L)_A \leq C_1 \lambda_{\ell-1}^{-1}(u_L, u_L)_A.
\]

This shows (19) and finishes the proof. \( \square \)

Remark 4.1. In [24, Lemma 9.2], a similar result to Theorem 4.7 is shown. There, the \( B_\ell \)-orthogonal projector is considered. That proof only holds for uniform grids. By using an \( L^2 \)-orthogonal projector, we avoid these difficulties. Since the convergence theory by Hackbusch [12] requires the error estimates for the \( B_\ell \)-orthogonal projector, this motivated us to use the convergence theory by Bramble [2], where this is not the case.

5 The smoothers and the overall convergence results

5.1 Subspace corrected mass smoother

We consider the subspace corrected mass smoother, which was originally proposed in [14] for a second order problem and was one of the first smoothers to produce a multigrid method for \( IgA \) which is robust in both the grid size and the spline degree. In [25, 24] this smoother was extended to biharmonic problems. The smoother is based around the inverse inequality in Theorem 4.5, which is independent of the spline degree.

First, we introduce a splitting for the one dimensional case as follows:

\[
S_{p,\tau} \cap H^1_0(0, 1) = S_{p,\tau}^0 \oplus S_{p,\tau}^1,
\]
where $S_{p,\tau}^0$ is as defined in (16) and $S_{p,\tau}^1$ is its $L^2$-orthogonal complement in $S_{p,\tau} \cap H_0^1(0,1)$. For each of these spaces, we define the corresponding $L^2$-orthogonal projection

$$Q_{p,\tau}^0 : H^2(0,1) \cap H_0^1(0,1) \to S_{p,\tau}^0,$$

$$Q_{p,\tau}^1 : H^2(0,1) \cap H_0^1(0,1) \to S_{p,\tau}^1.$$

The next step, is to extend the splitting to the multivariate case. Let $\alpha := (\alpha_1,\ldots,\alpha_d) \in \{0,1\}^d$ be a multiindex. The tensor product B-spline space $\tilde{V}_\ell = S_{\tau,\ell} \cap H_0^1(\bar{\Omega})$ with $\tau = (\tau_{\ell,1},\ldots,\tau_{\ell,d})$ is split into the direct sum of $2^d$ subspaces

$$\tilde{V}_\ell = \bigoplus_{\alpha \in \{0,1\}^d} S_{\tau,\ell}^\alpha \quad \text{where} \quad S_{\tau,\ell}^\alpha = S_{\tau_{\ell,1}}^{\alpha_1} \otimes \cdots \otimes S_{\tau_{\ell,d}}^{\alpha_d}. \quad (5.1)$$

Again, we define $L^2$-orthogonal projectors

$$\hat{Q}_{p,\tau}^\alpha : Q_{p,\tau}^\alpha = Q_{p,\tau_{\ell,1}}^{\alpha_1} \otimes \cdots \otimes Q_{p,\tau_{\ell,d}}^{\alpha_d} : \tilde{V} \to S_{p,\tau_{\ell}}^\alpha.$$

The projector $\hat{Q}_{p,\tau}^\alpha$ from Section 4.2 is consistent with this definition, for the choice $\alpha = 0$. Since the splitting is $L^2$-orthogonal, we obviously have the following result.

$$\hat{u}_\ell = \sum_{\alpha \in \{0,1\}^d} \hat{Q}_{p,\tau}^\alpha \hat{u}_\ell \quad \text{and} \quad \|\hat{u}_\ell\|_{L^2(\bar{\Omega})}^2 = \sum_{\alpha \in \{0,1\}^d} \|\hat{Q}_{p,\tau}^\alpha \hat{u}_\ell\|_{L^2(\bar{\Omega})}^2 \quad \forall \hat{u}_\ell \in \tilde{V}_\ell. \quad (5.2)$$

The next theorem shows that the splitting is also stable in $H^2$.

**Theorem 5.1.** Let $p \in \mathbb{N}$ with $p \geq 3$. Then there exists a constant $c > 0$ such that

$$c^{-1} \|\hat{u}_\ell\|_B^2 \leq \sum_{\alpha \in \{0,1\}^d} \|\hat{Q}_{p,\tau}^\alpha \hat{u}_\ell\|_B^2 \leq c \|\hat{u}_\ell\|_B^2 \quad \forall \hat{u}_\ell \in \tilde{V}_\ell.$$ 

**Proof.** Theorem 4.6 states the stability of $Q_{p,\tau}^0$ in the $H^2$-seminorm. The stability of $Q_{p,\tau}^1$ in the $H^2$-seminorm follows using the triangle inequality. The stability of these statements in the $L^2$-norm is obvious. From these observations, the right inequality follows by arguments that are completely analogous to those of the proof of Theorem 4.8. The left inequality follows from (23) and the triangle inequality. \qed

For notational convenience, we restrict the setup of the smoother to the two dimensional case. For notational convenience, we write the splitting (22) as

$$\tilde{V}_\ell = S_{p,\tau}^{00} \oplus S_{p,\tau}^{01} \oplus S_{p,\tau}^{10} \oplus S_{p,\tau}^{11}, \quad \text{where} \quad S_{p,\tau}^{01,02} = S_{p,\tau_{1,1}}^{01} \otimes S_{p,\tau_{1,2}}^{02}.$$

Following the ideas of [14] [25], we construct local smoothers $L_\alpha$ for any of the spaces $V_{\ell,\alpha} := S_{p,\tau}^{\alpha}$. These local contributions are chosen such that they satisfy the corresponding local condition

$$\bar{B}_{\ell,\alpha} + \beta \mathcal{M}_{\ell,\alpha} \leq L_{\ell,\alpha} \leq c(\bar{B}_{\ell,\alpha} + (\beta + h^{-4}) \mathcal{M}_{\ell,\alpha}).$$
where
\[ \mathcal{B}_{\ell,\alpha} := P_{\ell,\alpha}^T \mathcal{B}_{\ell,\alpha} P_{\ell,\alpha} \quad \text{and} \quad \mathcal{M}_{\ell,\alpha} := P_{\ell,\alpha}^T \mathcal{M}_{\ell,\alpha} P_{\ell,\alpha} \]
and \( P_{\ell,\alpha} \) is the matrix representation of the canonical embedding \( V_{\ell,\alpha} \rightarrow V_\ell \). The canonical embedding has tensor product structure, i.e., \( P_{\ell,\alpha_1} \otimes \cdots \otimes P_{\ell,\alpha_d} \), where the \( P_{\ell,\alpha_i} \) are the matrix representations of the corresponding univariate embeddings. In the two-dimensional case, \( \mathcal{B}_{\ell} \) and \( \mathcal{M}_{\ell} \) have the representation
\[ \mathcal{B}_{\ell} = B \otimes M + M \otimes B \quad \text{and} \quad \mathcal{M}_{\ell} = M \otimes M, \]
where \( B \) and \( M \) are the corresponding univariate stiffness and mass matrices (not necessarily equal for both spacial directions). For notational convenience, we do not indicate the spacial direction and the grid level for these matrices. Restricting \( \mathcal{B}_{\ell} \) to the subspace \( V_{\ell,(\alpha_1,\alpha_2)} \) gives
\[ \mathcal{B}_{\ell,(\alpha_1,\alpha_2)} = B_{\alpha_1} \otimes M_{\alpha_2} + M_{\alpha_1} \otimes B_{\alpha_2}, \]
where \( B_{\alpha_i} = P_{\ell,\alpha_i}^T B P_{\ell,\alpha_i} \) and \( M_{\alpha_i} = P_{\ell,\alpha_i}^T M P_{\ell,\alpha_i} \). We define
\[ \tilde{A}_{\ell} := \mathcal{B}_{\ell} + \beta \mathcal{M}_{\ell} \quad \text{and} \quad \tilde{A}_{\alpha_1,\alpha_2} := \mathcal{B}_{\alpha_1,\alpha_2} + \beta \mathcal{M}_{\alpha_1,\alpha_2}. \]
The inverse inequality for \( S_{p,\ell,\alpha}^0 \) (Theorem 4.5), allows us to estimate
\[ B_0 \leq \sigma M_0, \]
where \( \sigma = \sigma_0 h_{\ell,\min}^{-4} \) and \( \sigma_0 = 144 \). Using this, we define the smoothers \( L_{\alpha_1,\alpha_2} \) as follows and obtain estimates for them as follows:
\[
\begin{align*}
\tilde{A}_{00} & \leq (2\sigma + \beta)M_0 \otimes M_0 =: L_{00} \leq c(\tilde{A}_{00} + h^{-4}\tilde{M}_{00}), \\
\tilde{A}_{01} & \leq M_0 \otimes ((\sigma + \beta)M_1 + B_1) =: L_{01} \leq c(\tilde{A}_{01} + h^{-4}\tilde{M}_{01}), \\
\tilde{A}_{10} & \leq (B_1 + (\sigma + \beta)M_1) \otimes M_0 =: L_{10} \leq c(\tilde{A}_{10} + h^{-4}\tilde{M}_{10}), \\
\tilde{A}_{11} & = B_1 \otimes M_1 + M_1 \otimes B_1 + \beta M_1 \otimes M_1 =: L_{11} \leq c(\tilde{A}_{11} + h^{-4}\tilde{M}_{11}).
\end{align*}
\]
The extension to three and more dimensions is completely straight-forward (cf. (14)). For each of the subspaces \( V_{\ell,\alpha} \), we have defined a symmetric and positive definite smoother \( L_\alpha \). The overall smoother is given by
\[ L_\ell := \sum_{\alpha \in \{0,1\}^d} (Q_{D,\alpha})^T L_\alpha Q_{D,\alpha}, \]
where \( Q_{D,\alpha} = M_{\alpha}^{-1} P_{\ell,\alpha}^T \mathcal{M}_{\ell} \) is the matrix representation of the \( L^2 \)-projection from \( V_\ell \) to \( V_{\ell,\alpha} \). Completely analogous to (14) Section 5.2], we obtain
\[ L_\ell^{-1} = \sum_{\alpha \in \{0,1\}^d} P_{\ell,\alpha} L_\alpha^{-1} P_{\ell,\alpha}^T. \]
Theorem 5.2. Let $d \in \mathbb{N}$ and $p \in \mathbb{N}$ with $p \geq 3$. The subspace corrected mass smoother $L_\ell$, satisfies \[ (A_\ell u_\ell, u_\ell) \leq \frac{1}{\tau_\ell} (L_\ell u_\ell, u_\ell) \leq C_S \lambda_\ell ((A_\ell + h^{-4} M_\ell) u_\ell, u_\ell) \quad \forall u_\ell \in \mathbb{R}^{\dim V_\ell} \]
for all $\tau \in (0, \tau_0)$, where $\tau_0 > 0$ is some constant.

Proof. The inequality
\[(A_\ell u_\ell, u_\ell) \leq (L_\ell u_\ell, u_\ell) \leq c ((A_\ell + h^{-4} \bar{M}_\ell) u_\ell, u_\ell)\]
was shown in [23, Theorem 17] for $\beta = 0$. Note that no part of that proof requires uniform grids. So, the proof can be used almost verbatim also in the context of this paper. Using (23), the extension to $\beta > 0$ is straightforward. Using this and Lemma 2.1, we get
\[(A_\ell u_\ell, u_\ell) \leq d (A_\ell u_\ell, u_\ell) \leq \frac{d}{\tau_\ell} (L_\ell u_\ell, u_\ell) \leq c ((A_\ell + h^{-4} \bar{M}_\ell) u_\ell, u_\ell)\]
for some constant $c > 0$. Using (5), we obtain
\[(A_\ell u_\ell, u_\ell) \leq C_1 \frac{1}{\tau_\ell} (L_\ell u_\ell, u_\ell) \leq C_2 ((A_\ell + h^{-4} M_\ell) u_\ell, u_\ell)\]
for some constants $C_1, C_2 > 0$, which finishes the proof since $\lambda_\ell$ is bounded from below by a constant (Lemma 4.1). \qed

Corollary 5.1. Suppose that we solve the linear system (9) using a multigrid solver as outlined in Section 3 and using the subspace corrected mass smoother as outlined in Section 5, then the convergence of the multigrid solver is described by the relation
\[(I - B_{L_\ell}^2) A_{L_\ell} u_\ell, u_\ell \leq \left(1 - \frac{1}{C L}\right) (u_\ell, u_\ell)_{A_L}, \quad (5.3)\]
where the constant $C$ is independent of the grid sizes $h_\ell$, the number of levels $L$, the spline degree $p$ and the choice of the scaling parameter $\beta$. It may depend on $d$, the constants $c_1, c_2, c_q$, and $c_r$ and the shape of $\Omega$, cf. Notation 2.7.

Proof. We use Theorem 5.1, whose assumptions are shown by Theorem 4.9 and the combination of Lemma 5.1 and Theorem 5.2. \qed

Remark 5.1. The operator $L_{\ell}^{-1}$ can be applied efficiently because all of the local contributions $L_{00}$, $L_{01}$ and $L_{10}$ can be inverted efficiently because they are tensor products. For example, we have $L_{00}^{-1} = \frac{1}{25+\beta} (M_0^{-1} \otimes I)(I \otimes M_0^{-1})$, where both $M_0^{-1} \otimes I$ and $I \otimes M_0^{-1}$ can be realized by applying direct solvers for the univariate mass matrix to several right-hand sides. The operator $L_{11}$ is the sum of two tensor products. So, it has to be inverted as a whole. However, the dimension of the corresponding space is so small that the corresponding computational costs are negligible. More details on how to realize the smoother computationally efficient, are given in [14, Section 5]. There, it is outlined where an efficient realization of the subspace corrected mass smoother is also possible in case of more than two dimensions.
5.2 Symmetric Gauss-Seidel smoother and a hybrid smoother

The second smoother we consider is a symmetric Gauss-Seidel smoother consisting of one forward sweep and one backward sweep. It can be shown that this smoother satisfies Condition (15), where the constant $C_S$ depends on the spline degree, see [25]. This means that also the overall convergence result (24) holds, where again $C$ depends on the spline degree. The symmetric Gauss-Seidel smoother works well for domains with a nontrivial geometry transformations, but degenerated for large spline degrees (cf. [8, 16]).

Since the symmetric Gauss-Seidel smoother works well for nontrivial geometry transformations and the subspace corrected mass smoother is robust with respect to the spline degree, we combine these smoothers into a hybrid smoother, which was first introduced in [25]. This hybrid smoother consists of one forward Gauss-Seidel sweep, followed by one step of the subspace corrected mass smoother, finally followed by one backward Gauss-Seidel sweep.

6 Numerical experiments

In this section, we present the results of numerical experiments performed with the proposed algorithm. As computational domains, we first consider the unit square, then we consider the nontrivial geometries displayed in Figures 1 (two dimensional domain) and 2 (three-dimensional domain). We consider the problem

$$\beta u + \Delta^2 u = f \quad \text{in } \Omega,$$

$$u = g_1 \quad \text{on } \partial \Omega,$$

$$\Delta u = g_2 \quad \text{on } \partial \Omega,$$

where

$$f(x) = (\beta + d^2 \pi^4) \prod_{k=1}^{d} \sin(\pi x_k), \quad g_1(x) = \prod_{k=1}^{d} \sin(\pi x_k), \quad g_2(x) = -d \pi^2 \prod_{k=1}^{d} \sin(\pi x_k).$$

The discretization space on the parameter domain is the space of tensor-product B-splines. On the coarsest level ($\ell = 0$), we choose

$$\tau_{0,i} = (0, 1/3, 1/2, 2/3, 1), \quad \text{(6.1)}$$

for all spacial directions $i = 1, \ldots, d$. The discretization on level $\ell$ is obtained by performing $\ell$ uniform $h$-refinement steps. The spline spaces have maximum continuity and spline degree $p$. We solve the resulting system using the preconditioned conjugate gradient (PCG) with a V-cycle multigrid method with 1 pre and 1 post smoothing step, as preconditioner. A random initial guess is used and the stopping criteria is

$$\|r^{(k)}_L\| \leq 10^{-8} \|r^{(0)}_L\|,$$

where $r^{(k)}_L := \ell_L - A_L \ell^{(k)}_L$ is the residual at step $k$ and $\|\cdot\|$ denotes the Euclidean norm. All numerical experiments are implemented using the G+Smo library [17].
6.1 Numerical experiments on parameter domain

We start with the unit square as the domain, that is, \( \Omega = (0,1)^2 \). Note that \( g_1(x) = g_2(x) = 0 \) for this domain. For now, we consider the symmetric Gauss-Seidel smoother and the subspace corrected mass smoother. For both smoothers, we choose \( \tau = 1 \). The iteration counts are displayed in Table 1 for \( \beta = 1 \), and in Table 2 for \( \beta = 10^7 \).

Table 2: Iteration counts for 2D parametric domain, \( \beta = 10^7 \)

From the tables, we see that the symmetric Gauss-Seidel smoother preforms well for small spline degrees, but degenerates for larger spline degrees. These results are not surprising since it is known that standard smoothers do not work well for large spline degrees (cf. [8, 10]). Due to Corollary 5.1, the multigrid solver with subspace corrected mass smoother is robust with respect to the spline degree. The tables do reflex this. However, the iteration numbers are relatively high. Table 3 shows the iteration numbers when using an uniform grid with spacing \( 1/4 \) on the coarsest level (\( \ell = 0 \)), rather than
6 NUMERICAL EXPERIMENTS

the grid (25). The numbers in Table 3 are significantly smaller. This implies that the subspace corrected mass smoother is sensitive to the quasi-uniformity constant $c_q$.

6.2 Numerical experiments on physical domain

Now, we consider a domain with a nontrivial geometry transformation as displayed in Figures 1 and 2. The convergence of subspace corrected mass smoother degrades significantly due to the nontrivial geometry mapping. To combat this, we consider the hybrid smoother described in Section 5.2. Table 4 and Table 5 display the iteration numbers for the 2D and 3D physical domains, respectively. These iteration numbers are relatively small and seem to be robust with respect to both grid size and spline degree. Although the hybrid smoother is more expensive, as one smoothing step can be viewed as two smoothing steps, the reduction of iteration numbers outweighs this cost for larger spline degrees $p > 4$. For smaller spline degrees, the symmetric Gauss-Seidel smoother is ideal choice.

![Figure 1: The two-dimensional domain](image1)

![Figure 2: The three-dimensional domain](image2)

Remark 6.1. All experiments have also been performed for the choice $\beta = 0$. In this case, one obtains iteration numbers that are identical than those obtained for $\beta = 1$. Therefore, we chose to only display the results for $\beta = 1$.
